SPECTRAL PROPERTIES OF DISCRETE NEURAL FUNCTIONS OVER A GALOIS FIELD

Abstract. The paper deals with the discrete functions over a Galois field. We give the necessary and sufficient condition of discrete functions decomposition in group characters. The notion of neural element over a Galois field is introduced and the criterion of discrete functions realizability on a single neuron is proved in the paper. We also propose a spectral synthesis method over a finite field.

Keywords: neuron, spectral coefficient, structure vector, group character.

Introduction

Finite fields and groups are widely spread in the automata theory and logic [1-3]. They are particularly important in the coding theory [1]. It is shown in [4] that any finite automaton is isomorphic to the linear one over some finite field. Analysis and synthesis of linear automata over an arbitrary finite field are carried out by the traditional spectral analysis. It is shown in the paper that the basic methods of spectral analysis can be successfully used for the verification of discrete functions realizability by one neural element over a Galois field.

1. Spectral analysis of discrete functions over a Galois field

Let \( F = GF \left( p^n \right) \) be the Galois field containing cyclic groups

\[ H_{k_1} = \langle a_1 | a_1^{k_1} = 1 \rangle, \quad H_{k_2} = \langle a_2 | a_2^{k_2} = 1 \rangle, \quad \ldots, \quad H_{k_n} = \langle a_n | a_n^{k_n} = 1 \rangle \]

and \( G_n = H_{k_1} \otimes H_{k_2} \otimes \ldots \otimes H_{k_n} \) be the direct product of cyclic groups \( H_{k_i} \).

Let \( F = GF \left( p^n \right) \) be the Galois field containing cyclic groups

\[ H_{k_1} = \langle a_1 | a_1^{k_1} = 1 \rangle, \quad H_{k_2} = \langle a_2 | a_2^{k_2} = 1 \rangle, \quad \ldots, \quad H_{k_n} = \langle a_n | a_n^{k_n} = 1 \rangle \]

and \( G_n = H_{k_1} \otimes H_{k_2} \otimes \ldots \otimes H_{k_n} \) be the direct product of cyclic groups \( H_{k_i} \).

A mapping \( f : G_n \rightarrow F \) is a discrete \( n \)-variable function.

It should be noted that the spectral analysis of discrete functions \( f : G_n \rightarrow C \) over complex field is always possible because complex field contains the primitive \( k \)-th root of unity, where \( k \) is the least common multiple of \( k_1, k_2, \ldots, k_n \).

If \( F = GF \left( p^n \right) \), then the spectral analysis of discrete functions \( f : G_n \rightarrow C \) isn't
always possible. It is possible when the dimension of vector space $V^n_F = \{ f \mid f : G_n \rightarrow GF(p^n) \}$ and the order of character group $X(G_n)$ over fields $F$ are equal.

We consider the task of function $f : G_n \rightarrow F$ decomposition in characters of the $G_n$ group over $F$ field. If $k_1 = k_2 = \ldots = k_n = 2$ and $F$ is the field of real numbers $R$, then the characters group $X(G_n)$ of the group $G_n$ over field $R$ is equal to Hadamard-Walsh functions system and the spectral analysis is possible.

If $k_1 = k_2 = \ldots = k_n = k (k > 2)$ and the field $F$ is the complex field $C$, then the characters group $X(G_n)$ of the group $G_n$ over field $C$ is equal to Vilenkin-Krestenson functions system and the spectral analysis of discrete function is also possible.

Let $k = \text{lcm}(k_1, k_2, \ldots, k_n)$. It’s easy to show that if the field $F = GF(p^m)$ contains the primitive $k$-th root of unity, then $u = p^m - 1$ is multiple of $k$. Suppose that the field with the primitive element $\varepsilon$ contains the primitive $k$-root $\sigma$. Then the cyclic group $H_k = \{ \sigma \mid \sigma^k = 1 \}$ is the subgroup of field cyclic subgroup. Using the Lagrange theorem [5], we obtain that $k$ is the divisor of number $u$. Let’s consider $\sigma = \varepsilon^{uk}$ and prove that $\sigma$ is the primitive root of unity. Since $\varepsilon$ is the primitive in $F$, we have [6-8] that for all $i, j, r \in \{1, 2, \ldots, k - 1\}$, $\sigma^i \neq \sigma^j$, if $i \neq j$ and $\sigma^i \neq 1$. Therefore $k$ is the least natural number that $\sigma^k = 1$. So we can conclude that the spectral analysis of discrete function $f : G_n \rightarrow F$ is possible then and only then when $u$ is multiple of $k$.

Let’s find the analytic view of group $G_n$ characters over the field $F = GF(p^m)$. Let $k = \text{lcm}(k_1, k_2, \ldots, k_n)$, $\varepsilon$ be the primitive element of field $F = GF(p^m)$, $H_k = \{ a \mid a^k = 1 \}$ is the cyclic group of the order $k$, and $k$ is the divisor of the number $u$. Then for all $h_i \in H_{k_i}$ exists number $j_k \in \{0, 1, \ldots, k_i - 1\}$ such that $h_i = a_{i}^{j_k}$, where $a_i = a^{u/k_i}$ is the generating element of group $H_{k_i} (i = 1, 2, \ldots, n)$. The characters $\chi_{k_i}$ of the group $H_{k_i}$ over the field $F = GF(p^m)$ may be written as

$$\chi_{k_i}(h_i) = \sigma_{i}^{r_i j_{k_i}}, \quad (1)$$

where $\sigma_{i} = \varepsilon^{u/k_i}, r_i \in \{0, 1, \ldots, k_i - 1\}$. 
Since the group \( G_n \) is the direct product of cyclic groups \( H_{k_1}, \ldots, H_{k_n} \), for all \( g \in G_n \) there exist numbers \( j_i \in \{0, 1, \ldots, k_i - 1\}, i = 1, 2, \ldots, n \) such that \( g = (a_1^{j_1}, \ldots, a_n^{j_n}) = (a_1^{b_1/k_1}, \ldots, a_n^{b_n/k_n}) \).

The next formula follows from the multiplicative property of characters [6] and (1) concerning the general form of characters:

\[
\chi_{(\eta_1, \ldots, \eta_n)}(g) = \chi_{(\eta_1, \ldots, \eta_n)}(g) \cdot \chi_{(\eta_1, \ldots, \eta_n)}(g) = \chi_{(\eta_1, \ldots, \eta_n)}(g),
\]

where \( \sigma = e^{a/k} \), \( t_i = \frac{k_i}{k} \), \( r_i \in \{0, 1, \ldots, k_i - 1\}, i = 1, 2, \ldots, n \). It's possible to define the character product on the group \( G_n \) as follows:

\[
\forall g \in G_n \quad \chi_{(\eta_1, \ldots, \eta_n)}(g) \cdot \chi_{(\eta_1, \ldots, \eta_n)}(g) = \chi_{(\eta_1, \ldots, \eta_n)}(g),
\]

where \( \oplus_i \) is the \( k_i \)-addition. Thus we obtain the multiplicative character group \( X(G_n) \). We have the next consequence from (2): the number of different characters of group \( G_n \) over the field \( F \) is equal to the order of group \( G_n \). Then from the orthogonality of characters [6, 9] and from \( |X(G_n)| = \dim_F V^n = k_1 k_2 \ldots k_n \) we obtain that \( X(G_n) \) is the orthogonal basis of the space \( V^n_F \). Thus, an arbitrary \( f \in V^n_F \) can be uniquely written as follows:

\[
f(g) = \sum_{\eta = 0}^{k_i - 1} \ldots \sum_{\eta = 0}^{k_i - 1} s_{(\eta_1, \ldots, \eta_n)} \chi_{(\eta_1, \ldots, \eta_n)}(g),
\]

where addition and multiplication are considering in the field \( F \).

The decomposition (3) is called the spectral decomposition of discrete function \( f : G_n \rightarrow F \) in characters of \( G_n \) over the field \( F \).

Multiplying the both sides of (3) in \( \chi_{(\eta_1, \ldots, \eta_n)}^{-1} \) and summarizing by all elements of \( G_n \), we obtain the following equality

\[
\sum_{g \in G_n} f(g) \chi_{(\eta_1, \ldots, \eta_n)}^{-1}(g) = \sum_{g \in G_n} \left( \sum_{\eta = 0}^{k_i - 1} \ldots \sum_{\eta = 0}^{k_i - 1} s_{(\eta_1, \ldots, \eta_n)} \chi_{(\eta_1, \ldots, \eta_n)}(g) \right) \chi_{(\eta_1, \ldots, \eta_n)}^{-1}(g).
\]

Subject to the orthogonality of characters the right side of last equality can be written as follows:
\[
\sum_{g \in G_n} \left( \sum_{\tau_i=0}^{k_i-1} \cdots \sum_{\tau_n=0}^{k_n-1} \chi_{(\tau_1, \ldots, \tau_n)}(g) \right) \chi_{(q_1, \ldots, q_n)}^{-1}(g) = \\
= \sum_{\tau_i=0}^{k_i-1} \cdots \sum_{\tau_n=0}^{k_n-1} \left( \sum_{g \in G_n} \chi_{(\tau_1, \ldots, \tau_n)}(g) \right) \chi_{(q_1, \ldots, q_n)}^{-1}(g) = s_{(q_1, \ldots, q_n)} |G_n|.
\]

Therefore, the spectral coefficients of the function can be obtained with following formula

\[
s_{(q_1, \ldots, q_n)} = |G_n|^{-1} \sum_{g \in G_n} f(g) \chi_{(q_1, \ldots, q_n)}^{-1}(g), \tag{4}
\]

where \( q_i \in \{0,1,\ldots,k_i-1\} \) (\( i \in \{1,2,\ldots,n\} \)).

Note. The calculation of spectral coefficients \( s_{(q_1, \ldots, q_n)} \) of discrete function \( f \in V^n_f \) can be done by using the quick algorithms issuing from matrices factorization method [10] and the well-known theorem of the theory of representations [9]: if \( G_n = H_{k_1} \otimes H_{k_2} \otimes \ldots \otimes H_{k_n} \) and \( |G_n| \) is the divisor of \( p^m - 1 \), then \( X(G_n) = X(H_{k_1}) \otimes X(H_{k_2}) \otimes \ldots \otimes X(H_{k_n}) \) over \( GF(p^m) \) field.

2. Discrete neural functions over a Galois field

In this section we introduce the notion of neuron over field \( GF(p^m) \) and give the criterion of discrete functions realizability by single neuron over a Galois field.

Let \( k_1, k_2, \ldots, k_n, q \) be natural numbers \((k_i \geq 2, i = 1, \ldots, n, q \geq 2)\) and \( k = \text{lcm}(k_1, k_2, \ldots, k_n, q) \). We consider only finite fields \( F = GF(p^m) \) satisfying the following condition: \( p^m - 1 \) is exactly divided by \( k \). It means that field \( F = GF(p^m) \) contains cyclic groups \( H_{k_1}, H_q \) with respective group generators \( \sigma_i = \varepsilon^{u/k_i} \) \((i = 1, 2, \ldots, n)\), \( \sigma = \varepsilon^{u/q} \), where \( \varepsilon \) is the primitive element of field \( F \), \( u = p^m - 1 \).

Define the function \( \text{Fsign} \xi \) on \( F \setminus \{0\} \) as follows:

\[\forall \xi \in F \setminus \{0\} \ \text{Fsign} \xi = \sigma^j, \ \text{if} \ \frac{ju}{q} \leq \deg \xi < \frac{(j+1)u}{q},\]

where \( \deg \xi \) is the degree of element \( \xi (\xi = \varepsilon^{\deg \xi}) \), \( j \in \{0,1,\ldots,q-1\} \).

A neuron over field \( F = GF(p^m) \) is a logical unit with \( n+1 \) inputs \( x_1, \ldots, x_n; x_0 \) \((n \geq 1)\) taking values respectively from cycling group \( H_{k_i} \) \((i = 1, \ldots, n)\) and
\( H_0 = \{ 1 \} \), and a single output taking value from the group \( H_q \). Weights \( \omega_i \) from the field \( F \) correspond to respective inputs \( x_i \). The output of unit is obtained as the result of sign-function \( \text{Fsign}(\xi) \) on “weighted sum” \( \omega_1 x_1 + ... + \omega_n x_n + \omega_0 \) of inputs as Fig. 1 illustrates.

![Diagram of a neuron] Fig. 1. A representation of neuron over a Galois field

The vector \( \mathbf{w} = (\omega_1, ..., \omega_n; \omega_0) \) is called the structure vector of neuron over a Galois field \( \left( \omega_i \in GF \left( p^m \right) \right) \).

Let \( G_n = H_{k_1} \oplus H_{k_2} \oplus ... \oplus H_{k_n} \) be a direct product of cyclic groups \( H_{k_i} \). A discrete function \( f : G_n \to H_q \) is realizable by a single neuron over field \( F = GF \left( p^m \right) \) if exists \((n+1)\)-dimensional vector \( \mathbf{w} = (\omega_1, ..., \omega_n; \omega_0) \) such that for all \( \mathbf{g} = (\gamma_1, ..., \gamma_n) \in G_n \), \( f(\mathbf{g}) = \text{Fsign}(\mathbf{w}) \), where \( \mathbf{w}(\mathbf{g}) = \omega_1 \gamma_1 + ... + \omega_n \gamma_n + \omega_0 \). A discrete function \( f : G_n \to H_q \) realizable on a single neuron over field \( F \) is called a neural function over \( F \).

Let \( f : G_n \to H_q \) be an arbitrary discrete function. The question arises about realizability of \( f \) by a single neuron over field \( F = GF \left( p^m \right) \) and synthesis of structure vector \( \mathbf{w} = (\omega_1, ..., \omega_n; \omega_0) \) of a corresponding neuron.

Let \( X^*(G_n) = \left\{ \chi_{(0,0,0,0,0)}, \chi_{(1,0,0,0,0)}, \chi_{(0,1,0,0,0)}, ..., \chi_{(0,0,1,0,0)}, \chi_{(0,0,0,1,0)} \right\} \).

**Theorem 1.** A discrete function \( f : G_n \to H_q \) is realizable by a single neuron over field \( F = GF \left( p^m \right) \) with the structure vector \( \mathbf{w} = (\omega_1, ..., \omega_n; \omega_0) \) if and only if there exists \( r : G_n \to F \setminus \{0\} \) such that
0 ≤ \deg r(x) < \frac{u}{q}, \quad (5)

and

( r(x) f(x), \chi^{-1}(x) ) = 0, \quad (6)

for all \( \chi \in X(G_n) \setminus X^*(G_n) \), where \((a,b)\) is the standard inner product of vectors \(a\) and \(b\).

**Proof.** At first we shall prove the necessity of the conditions. A discrete function \( f: G_n \to H_q \) is realizable over \( F \) by a single neuron with the structure \( w = (\omega_1, \ldots, \omega_n; \omega_b) \). That is

\[
\forall g \in G_n \quad f(g) = \text{Fs}gnw(g). \quad (7)
\]

Construct the function \( r(g) \) in the following way: for all \( g \in G_n \) assume

\[
\deg r(g) = \deg w(g) - \deg f(g). \quad (8)
\]

Then \( \deg w(g) = \deg r(g) + \deg f(g) \) and for an arbitrary \( g \in G_n \)

\[
f(g)r(g) = \omega_b + \omega_1x_1(g) + \cdots + \omega_nx_n(g). \quad (9)
\]

Suppose that the value of \( f \) on an arbitrary fixed element \( g \in G_n \) is \( \sigma^j \). Then from (7) follows

\[
\frac{ju}{q} \leq \deg w(g) < \frac{(j+1)u}{q}. \quad (10)
\]

The inequality (10) can be written as follows:

\[
\frac{ju}{q} - \deg f(g) \leq \deg w(g) - \deg f(g) < \frac{(j+1)u}{q} - \deg f(g).
\]

From the last inequality, (8) and

\[
de g f (g) = \frac{ju}{q}, \quad \quad (f(g) = \sigma^j = e^{iuj/q}) \quad \text{follows} \quad 0 \leq \deg r(g) < \frac{u}{q}.
\]

Now we give the proof of the sufficiency of the theorem condition. Let us assume that for \( f: G_n \to H_q \) exists a function \( r: G_n \to F \setminus \{0\} \) satisfying conditions (5) and (6). We can expand the function \( r(x)f(x) \in V^n_F \) in characters of group \( G_n \) over field \( F \). In
consideration of (6) and \( \forall x \in \mathcal{X}(G_n) \setminus \mathcal{X}^+(G_n) \), \( s_x = |G_n|^{-1}(r(x)f(x), \mathcal{X}^{-1}(x)) \) we have \( s_x = 0 \). It means

\[
r(x)f(x) = \sum_{x \in \mathcal{X}(G_n)} s_x \mathcal{X}(x).
\]

The equality (11) can be written as follows:

\[
r(x)f(x) = s_{(0,\ldots,0)}\mathcal{X}_{(0,\ldots,0)}(x) + s_{(1,\ldots,0)}\mathcal{X}_{(1,\ldots,0)}(x) + \cdots + s_{(0,\ldots,1)}\mathcal{X}_{(0,\ldots,1)}(x),
\]
or

\[
r(x)f(x) = \alpha_0 + \alpha_1\mathcal{X}_{(1,\ldots,0)}(x) + \cdots + \alpha_n\mathcal{X}_{(0,\ldots,1)}(x).
\]

According to our definition \( \mathcal{X}_{(1,\ldots,0)}(x) = x_1(x), \ldots, \mathcal{X}_{(0,\ldots,1)}(x) = x_n(x) \). Thus,

\[
r(x)f(x) = w(x).
\]

The direct consequence from (13) is the fact that for all \( g \in G_n \)

\[
\deg r(g) = \deg w(g) - \deg f(g).
\]

Condition (5) implies that

\[
0 \leq \deg w(g) - \deg f(g) < \frac{\mu}{q}.
\]

Let \( g \) is an arbitrary element in \( G_n \) and \( f(g) = \sigma^j \). Then

\[
\deg f(g) = \frac{uj}{q}
\]

and from (14) follows

\[
\frac{uj}{q} \leq \deg w(g) < \frac{u(j+1)}{q}.
\]

So, for all \( g \) in \( G_n \), \( f(g) = F\text{sign}w(g) \), that proves the sufficiency of theorem conditions.

If a discrete function \( f : G_n \rightarrow H_q \) satisfies all conditions of theorem 1, then the coordinates of the structure vector \( w = (\omega_1, \ldots, \omega_m; \omega_0) \) of the neuron, realizing \( f \) over field \( F \), can be found as follows:
\[ \omega_0 = [G_n]^{-1} \left( r(x) f(x), \chi_{(0,...,0)}(x) \right), \]
\[ \omega_i = [G_n]^{-1} \left( r(x) f(x), \chi_{(1,0,...,0)}(x) \right), \]
\[ \omega_n = [G_n]^{-1} \left( r(x) f(x), \chi_{(0,...,0,\delta)}(x) \right). \]

(15)

**Example.** Let \( n = 2, k_1 = 2, k_2 = q = 3 \) i \( G_2 = H_2 \otimes H_3 \). Then \( k = \text{lcm}(2,3,3) \). So, we can use \( GF(13) \) as \( F \) with 2 as the primitive element of \( F \), that is \( GF(13) \backslash \{0\} = \{2^j \mid j = 0,1,...,11\} \). The group generators of groups \( H_2,H_3 \) over \( F \) are correspondently \( \sigma_1 = 2^{12/2} = 12 \) and \( \sigma_2 = 2^{12/3} = 3 \), and the range of values of function \( f : G_n \rightarrow H_q \) is the set \( \{1,3,9\} \). Table 1 can be used for value assignment of functions \( f : G_n \rightarrow H_q \), \( r : G_n \rightarrow F \backslash \{0\} \) and the character group \( X(G_2) \) of group \( G_2 \) over \( F \):

</tbody>
</table>

On the basis of theorem 1 and table 1 we can write the following linear equation system over \( F \):

\[
\begin{align*}
0 + 3r_1 + r_2 + 3r_3 + r_4 + 3r_5 &= 0, \\
r_0 + 9r_1 + 9r_2 + 10r_3 + 10r_4 + 12r_5 &= 0, \\
r_0 + 3r_1 + r_2 + 10r_4 + 12r_5 &= 0,
\end{align*}
\]

\( r_0, r_1, r_2, r_3, r_4, r_5 \in \{1,2,4,8\} \). The last system has several solutions, one of these is \( (1,8,1,1,4,2) \). This system solution may be use for finding the structure vector of the neuron, realizing the function \( f \):
\[
\begin{align*}
\omega_0 &= 11 \cdot (1 + 8 + 3 + 3 + 36 + 18) = 11 \cdot 4 = 5, \\
\omega_1 &= 11 \cdot (1 + 8 + 3 \cdot 3 + 3 + 36 \cdot 12 + 18 \cdot 12) = 11 \cdot 7 = 12, \\
\omega_2 &= 11 \cdot (1 + 72 + 9 + 3 + 9 \cdot 4 + 9 \cdot 3 \cdot 2) = 11 \cdot 8 = 10.
\end{align*}
\]

Therefore, \( f(x_1, x_2) = F\text{sign}(12x_1 + 10x_2 + 5). \)

The design of neuron synthesis methods for partially specific discrete functions is very important in practice, because this task often arises in many applications, such as pattern recognition, diagnostics and talk synthesis.

Let a discrete function \( f : G_n \rightarrow H_q \) be not fully defined on group \( G_n \). We shall denote \( D_n \subset G_n \) the set of elements, in which the value of the function \( f \) is well defined and let \( D_n' = G_n \setminus D_n \) be the set of elements in which the function \( f \) is undefined.

The partially defined discrete function \( f : G_n \rightarrow H_q \) is realizable on a single neuron over the field \( F \) if exists \((n+1)\)-dimensional vector \( w = (\omega_1, \ldots, \omega_n; \omega_0) \) such that for all \( g \in D_n \) \( f(g) = F\text{sign}w(g) \).

**Theorem 2.** A partially defined discrete function \( f : G_n \rightarrow H_q \) is realizable on a single neuron over field \( F = GF\left(p^m\right) \) with the structure vector \( w \) if such well defined functions \( r : G_n \rightarrow F \setminus \{0\} \), \( h : G_n \rightarrow H_q \) exist, that the restriction of \( h \) on \( D_n \) coincides with \( f \) and for all \( x \) in \( D_n \) the following conditions are satisfied

\[
0 \leq \deg r(x) < \frac{u}{q},
\]

\[
\left(r(x)f(x), \chi^{-1}(x)\right) = 0,
\]

where \( \chi \in X(G_n) \setminus X^*(G_n) \).

The proof results from theorem 1.

The class of discrete functions realizable on a single neuron depends on selected Galois field. The computer modeling of synthesis neurons over a finite field \( F \) proves that increasing of the cardinality of the field \( F \) implies that the cardinality of the class of neural functions does not decrease. The following example confirms the last claim. Let \( n = 2, k_1 = k_2 = q = 2 \) i \( F = GF(3) \). The number \( u \) is multiple of \( k = \text{lcm}(k_1, k_2, q) \), thus the spectral analysis of Boolean functions over \( F \) is possible. It is evident that \( \varepsilon = 2 \) is the primitive element of the field \( F \). All Boolean neural functions of two variables over \( F \) are given in the following table.

The respective structure vectors are $w_{g_0} = (0,0;1)$, $w_{g_1} = (1,0;0)$, $w_{g_2} = (0,1;0)$, $w_{g_3} = (0,0;2)$, $w_{g_4} = (2,0;0)$ and $w_{g_5} = (0,2;0)$. Thus, the class of Boolean neural functions of two variables over $GF(3)$ contains six functions $g_0, g_1, g_2, g_3, g_4, g_5$.

Let us consider the field $F = GF(5)$. It is possible to take $\varepsilon = 2$ as a primitive element Then $\sigma = \varepsilon ^{\frac{5-1}{2}} = 4$. The Boolean neural functions of two variables over $GF(5)$ are given in Table 3.

</table>

The respective structure vectors are $w_{f_0} = (0,0;1)$, $w_{f_1} = (2,2;2)$, $w_{f_2} = (2,3;2)$, $w_{f_3} = (1,0;0)$, $w_{f_4} = (3,2;2)$, $w_{f_5} = (0,1;0)$, $w_{f_6} = (1,1;4)$, $w_{f_7} = (2,2;3)$, $w_{f_8} = (3,3;2)$, $w_{f_9} = (4,4;1)$, $w_{f_{10}} = (0,4;0)$, $w_{f_{11}} = (2,3;3)$, $w_{f_{12}} = (4,0;0)$, $w_{f_{13}} = (3,2;3)$, $w_{f_{14}} = (3,3;3)$, $w_{f_{15}} = (0,0;4)$.

We see that all two variable Boolean function are realizable over $GF(5)$. The field $GF(5)$ is the minimal Galois field (by cardinality) having the mentioned property.

Let $k = \text{lcm}(k_1, \ldots, k_n, q)(k_j \geq 2, q \geq 2)$ and $G_n = H_{k_1} \otimes \ldots \otimes H_{k_n}$.

**Hypothesis.** For any $k$ and $n$ there exists minimal Galois field $F_{\text{min}}$ such that all functions $f : G_n \rightarrow H_q$ are realizable on single neuron over which.

**Conclusions**

The effective synthesis method of many valued neurons over a Galois field is designed on the basis of spectral analysis of discrete functions. This method can be used for
solving practical problems, such as information encoding, data compression, data communication, classification, pattern recognition, etc.
